

OC Core 1.3.2 Journal Core

Release-Bound Scientific Kernel for Collapse, Residue, Rebirth, and Evidence-Scoped Continuity

Alexander Yashin

ORCID 0009-0008-6166-0914

Version v1.3.2; release date: 28.04.2026

Abstract

This journal-core artifact states the compact scientific kernel of OC Core 1.3.2. It is not a replacement for the master monograph; it is the release-bound article spine that a reviewer can read first. The central result is a source-audited grammar for collapse, residue, and rebirth of continua, together with explicit evidence boundaries for theorem-native, operational, simulation, and frontier claims. OC Core 1.3.2 includes the terminal release-blocker ledger, K0–K12 projection state, DRT strict-salvage state, Tsukrov repair, Parfitian Cerberus pass, LRGEF release state, and night-delta integration as bounded public-safe release artifacts.

Release Identity

OC Core 1.3.2 is the current stable no-send baseline of the Core 1.3 line. It is prepared for owner review and package audit, not for automatic public publication. Public release, DOI minting, Zenodo upload, GitHub release creation, and outbound announcements remain locked until explicit owner approval and publication-gate review.

Scientific Kernel

The release kernel has four load-bearing notions:

- admissible realization: a state or fiber region that keeps a continuum live under its declared threshold and embedding regime;
- collapse/death: the loss of every admissible realization under that regime;
- residue: post-collapse structure that may remain without preserving live identity;
- rebirth: a later live continuum grounded in residue but not identical with the original continuum.

The defended classification claim is therefore bounded: within the audited OC Core kernel, when a continuum loses every admissible realization, the original continuum is dead; surviving structure is residue, and later residue-grounded life is rebirth rather than persistence of the original continuum.

Evidence Boundary

OC Core 1.3.2 separates claim support into release-visible classes. The master monograph carries theorem-roadmap references and proof-machinery anchors; the release packet carries evidence ledgers, replay manifests, domain projection state, and reviewer-navigation materials. The package does not claim unbounded predictive authority, full replacement of domain science, or completion of every possible extension theorem.

Release-Integrated Science

Surface	Role in 1.3.2
Master monograph	Canonical theory, definitions, theorem roadmap, proof machinery, and evidence boundaries.
Science blocker closure ledger	Release terminality ledger for the eighty-two tracked release blockers; it records proof/evidence, replay, and owner-gate terminal routes without treating mere administrative notes as science.
K0–K12 projection state	Domain projection/replay status across mathematics, physics, chemistry, biology, systems/civilizational projection, and metaontology.
DRT strict salvage	Strict-salvage status: DRT-derived material is not promoted into Core authority without reproducibility and Core-gate reconciliation.
Tsukrov repair	Evidence-first response surface for the Stanislav Tsukrov review packet, using bounded public summaries and release-safe references.
Parfitian Cerberus	Ethical and release-governance audit layer for no-send release readiness.
LRGEF	Release governance, manifest, provenance, ZIP integrity, version consistency, and no-send publication lock.

What This Article Does Not Claim

This article imports the public-safe formal and benchmark elements prepared for the OC 1.4 line when they already have proof, replay, or gate support: observation architecture, event/fact contract, support classes, quantum/no-signalling boundary, IMN baseline treatment, and the deterministic ten-task benchmark suite. It does not include private IP material, private reviewer-source material, private model transcripts, account credentials, local filesystem paths, or draft-only internal research. It does not use unsupported theorem labels or unsupported prediction language. Quantitative claims require protocol, code, data or fixture, output hash, tolerance envelope, and falsifier.

Reviewer Reading Order

A reviewer should start with this journal core, then read the master monograph front matter and theorem roadmap, then inspect the release dossier, PDF quality report, science blocker closure ledger, K0–K12 projection packet, DRT strict-salvage packet, Tsukrov repair packet, and Parfit/LRGEF gate reports. That reading order keeps the scientific claim, the evidence route, and the publication lock visible at the same time.

Reader-Specific Navigation

Reader	Primary question
Owner	Is the package honest enough for public review after the no-send locks are explicitly released?
Mathematical reviewer	Are identity, collapse, residue, and rebirth tied to stable definitions and theorem-fate routes?
Domain reviewer	Are the domain projections bounded by replay state rather than treated as domain replacement?
Reproducibility reviewer	Can every package claim be traced to source, manifest, hash, data, or gate output?
Publication reviewer	Are all external actions still locked until owner and channel approval?

Proven, Replayed, Future

Class	Release treatment
Proven or evidence-closed	The Core kernel, theorem-fate rows, source-audited support classes, and terminal blocker ledger.
Replayed	K0–K12 domain projection routes, benchmark/replay manifests, simulation-result records, and DRT workflow/salvage checks.
Outside 1.3.2	IP-sensitive invention review, unrelated-domain claims, broader empirical protocols, and owner-gated publication actions.

Minimal Scientific Claim

The minimal scientific claim of this release is not that OC has finished every possible theorem. It is that the Core 1.3.2 package now exposes a coherent, evidence-scoped ontology of continua with release-visible boundaries. A reviewer can inspect where a claim is formal, where it is replayed, where it is structural, and where a later release must do more work.

Publication Boundary

The journal core is publication-ready only as part of the owner-reviewed release package. It does not authorize publication by itself, and it does not widen any claim beyond the release manifest, claim ledger, support map, and no-send governance state.

Release Inspection Appendix A: Claim Support

Claim type	Required support in 1.3.2
Identity and continuity	Definition route in the master monograph, source-audited terminology, and theorem-fate row when stated formally.
Collapse/death	Explicit admissible-realization criterion and support in the Core kernel.
Residue	Bounded post-collapse classification, with no claim that residue preserves live identity.
Rebirth	Later live structure grounded in residue, explicitly not identical with the collapsed original.
Domain projection	K/domain packet, replay status, source-native inclusion verdict, and structural-only boundary where quantitative replay is absent.
Publication readiness	LRGEF, Parfitian Cerberus, manifest/checksum integrity, and owner no-send lock.

Release Inspection Appendix B: Reviewer Questions

1. Does the release define its central terms before using them as claims?
2. Does each strong theorem, prediction, or promotion word have a support-map row?
3. Does each domain extension remain bounded by its K/domain projection state?
4. Does the package keep private review material and model transcripts outside the public bundle?
5. Does the publication package remain no-send until owner/channel unlock?

Positive answers to these questions do not make OC final. They make this release inspectable, citable after approval, and scientifically bounded.

Release Inspection Appendix C: What Would Be Misleading

It would be misleading to market this release as an unbounded predictive engine or as authority over unrelated problem classes. The correct public posture is strong and precise: OC Core 1.3.2 includes a global verdict-invariant minimality theorem for OC-compatible representations, deterministic benchmark support for the admitted forward layer, visible evidence routes, a terminal blocker ledger, and explicit owner/publication locks.
